Section Overview

Arrays and Vectors

- Arrays
 - What they are
 - •Why we use arrays
 - Declaration and initialization
 - Accessing array elements
- •Multi-dimensional arrays
- Vectors
 - What they are
 - Advantages vs. arrays
 - Declaration and initialization

BEGINNING C++ PROGRAMMING Section Overview

What is an array?

- •Compound data type or data structure
 - Collection of elements
- •All elements are of the same type
- •Each element can be accessed directly

BEGINNING C++ PROGRAMMING What is an Array?

Why do we need arrays?

```
int test_score_1 {0};
int test_score_2 {0};
int test_score_3 {0};
```

BEGINNING C++ PROGRAMMING What is an Array?

Why do we need arrays?

```
int test_score_1 {0};
int test_score_2 {0};
int test_score_3 {0};
int test_score_4 {0};
int test_score_5 {0};
. . .
int test_score_100 {0};
```

BEGINNING C++ PROGRAMMING What is an Array?

Characteristics

- Fixed size
- •Elements are all the same type
- Stored contiguously in memory
- •Individual elements can be accessed by
- •their position or index
- •First element is at index 0
- •Last element is at index size-1
- •No checking to see if you are out of bounds
- Always initialize arrays
- Very efficient
- •Iteration (looping) is often used to process

test_scores

100	[0]
95	[1]
87	[2]
80	[3]
100	[4]
83	[5]
89	[6]
92	[7]
100	[8]
95	[9]
	ı

BEGINNING C++ PROGRAMMING What is an Array?

Declaring

```
Element_Type array_name [constant number of elements];
```

```
int test_scores [5];
int high_score_per_level [10];
const int days_in_year {365};
double hi_temperatures [days_in_year];
```

BEGINNING C++ PROGRAMMING
Declaring and Initializing Arrays

Initialization

```
Element_Type array_name [number of elements] {init list}
```

BEGINNING C++ PROGRAMMING
Declaring and Initializing Arrays

Accessing array elements

```
array_name [element_index]

test_scores [1]
```

```
int test_scores [5] {100,95,99,87,88};

cout << "First score at index 0: " << test_scores[0] << endl;
cout << "Second score at index 1: " << test_scores[1] << endl;
cout << "Third score at index 2: " << test_scores[2] << endl;
cout << "Fourth score at index 3: " << test_scores[3] << endl;
cout << "Fifth score at index 4: " << test_scores[4] << endl;</pre>
```

BEGINNING C++ PROGRAMMING
Accessing Array Elements

Changing the contents of array elements

```
array_name [element_index]
```

BEGINNING C++ PROGRAMMING
Accessing Array Elements

How does it work?

- •The name of the array represent the location of the first element in the array (index 0)
- •The [index] represents the offset from the beginning of the array
- •C++ simply performs a calculation to find the correct element
- •Remember no bounds checking!

Declaring multi-dimensional arrays

```
Element_Type array_name [dim1_size][dim2_size]
```

```
int movie_rating [3][4];
```

BEGINNING C++ PROGRAMMING Multidimensional Arrays

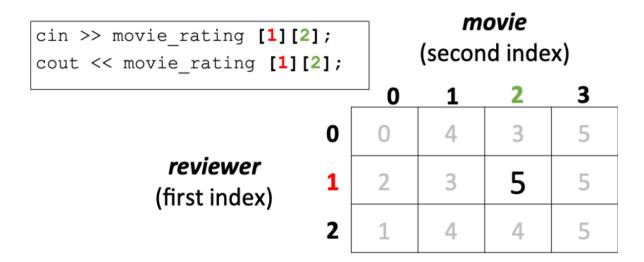

Multi-dimensional arrays

```
const int rows {3};
                                           movie
const int cols {4};
                                      (second index)
int movie_rating [rows][cols];
                                   0
                             0
                                                3
                                                      5
                                  0
                                         4
               reviewer
                                  2
                                         3
                                                3
                                                      5
              (first index)
                                                      5
                                  1
                                         4
                                                4
```

BEGINNING C++ PROGRAMMING Multidimensional Arrays

Accessing array elements in multi-dimensional arrays

BEGINNING C++ PROGRAMMING Multidimensional Arrays

Initializing multi-dimensional arrays

```
int movie_rating [3][4]
{
      { 0, 4, 3, 5},
      { 2, 3, 3, 5},
      { 1, 4, 4, 5}
};
```

	0	1	2	3
0	0	4	3	5
1	2	3	3	5
2	1	4	4	5

BEGINNING C++ PROGRAMMING Multidimensional Arrays

- Suppose we want to store test scores for my school
- •I have no way of knowing how many students will register next year
- Options:
 - •Pick a size that you are not likely to exceed and use static arrays
 - •Use a dynamic array such as vector

What is a vector?

- Container in the C++ Standard Template Library
- •An array that can grow and shrink in size at execution time
- Provides similar semantics and syntax as arrays
- Very efficient
- Can provide bounds checking
- •Can use lots of cool functions like sort, reverse, find, and more.

Declaring

```
#include <vector>
using namespace std;

vector <char> vowels;

vector <int> test_scores;
```

BEGINNING C++ PROGRAMMING What is a Vector?

Declaring

```
vector <char> vowels (5);
vector <int> test_scores (10);
```

BEGINNING C++ PROGRAMMING What is a Vector?

Initializing

```
vector <char> vowels {'a' ,'e', 'i', 'o', 'u' };
vector <int> test_scores {100, 98, 89, 85, 93};
vector <double> hi_temperatures (365, 80.0);
```

BEGINNING C++ PROGRAMMING What is a Vector?

Characteristics

- Dynamic size
- •Elements are all the same type
- •Stored contiguously in memory
- •Individual elements can be accessed by
- •their position or index
- •First element is at index 0
- •Last element is at index size-1
- •[] no checking to see if you are out of bounds
- •Provides many useful function that do bounds check
- •Elements initialized to zero
- Very efficient
- •Iteration (looping) is often used to process

BEGINNING C++ PROGRAMMING What is a Vector?

Accessing vector elements – array syntax

```
vector_name [element_index]

test_scores [1]
```

```
vector <int> test_scores {100,95,99,87,88};

cout << "First score at index 0: " << test_scores[0] << endl;
cout << "Second score at index 1: " << test_scores[1] << endl;
cout << "Third score at index 2: " << test_scores[2] << endl;
cout << "Fourth score at index 3: " << test_scores[3] << endl;
cout << "Fifth score at index 4: " << test_scores[4] << endl;</pre>
```

BEGINNING C++ PROGRAMMING Accessing and Modifying Vector elements

Accessing vector elements - vector syntax

```
vector_name.at(element_index)
test_scores.at(1)
```

```
vector <int> test_scores {100,95,99,87,88};

cout << "First score at index 0: " << test_scores.at(0) << endl;
cout << "Second score at index 1: " << test_scores.at(1) << endl;
cout << "Third score at index 2: " << test_scores.at(2) << endl;
cout << "Fourth score at index 3: " << test_scores.at(3) << endl;
cout << "Fifth score at index 4: " << test_scores.at(4) << endl;</pre>
```

BEGINNING C++ PROGRAMMING
Accessing and Modifying Vector elements

Changing the contents of vector elements – vector syntax

```
vector_name.at(element_index)
```

```
vector <int> test_scores {100,95,99,87,88};

cin >> test_scores.at(0);
cin >> test_scores.at(1);
cin >> test_scores.at(2);
cin >> test_scores.at(3);
cin >> test_scores.at(4);

test_scores.at(0) = 90;  // assignment statement
```

BEGINNING C++ PROGRAMMING Accessing and Modifying Vector elements

So, when do they grow as needed?

```
vector_name.push_back(element)
```

Vector will automatically allocate the required space!

BEGINNING C++ PROGRAMMING
Accessing and Modifying Vector elements

What if you are out of bounds?

- Arrays never do bounds checking
- •Many vector methods provide bounds checking
- •An exception and error message is generated

```
vector <int> test_scores { 100,95 };

cin >> test_scores.at(5);

terminate called after throwing an instance of 'std::out_of_range'
what(): vector::_M_range_check: __n (which is 5) >= this->size() (which is 2)
This application has requested the Runtime to terminate it in an unusual way.
Please contact the application's support team for more information.
```
